

# Arrays & Pointers

CST 357/457 – Systems Programming  
Michael Ruth, Ph.D.  
Associate Professor  
Computer Science & I.T.  
mruth@roosevelt.edu

---

---

---

---

---

---

---

## Objectives

- Discuss arrays and their use in C
- Explain pointers including notation, declarations, use, and dereferencing
- Discuss pointers in relation to arrays
- Explain functions use of pointers including pointers to functions
- Discuss complicated pointer declarations

CST 357/457 Systems Programming  
Introduction to Arrays & Pointers  
Reading: TBD

Michael Ruth, Ph.D.

# Arrays

- Introduction
- Definition
- An Example
- Passing Arrays to Functions
- Another Example
- More Dimensional Arrays

---

---

---

---

---

---

---

---

# Array Introduction

- Arrays are **contiguous** group of variables with the same name and the same type
  - The contiguous is ultra-important as it is this very quality that makes arrays ultra-fast!
- The individual elements of an array are indexed such that to refer to a specific element we provide a position number of that particular element
  - Positions begin at zero in C (just like Java)
- They are referenced using subscripts
  - EX: `a [ 0 ]` refers to the 0<sup>th</sup> element
  - This subscript **must** be an integer or integer expression

---

---

---

---

---

---

---

---

# Array Definition

- Arrays are defined using the following format:
  - **type name[<number of elements>];**
- Just as we could with other variable types we can initialize using a literal.
  - We do so using a comma separated list surrounded by braces {}
    - EX:
      - `int x[3] = {1,2,3};`
      - If we have too few numbers, the rest are initialized to zero (very useful!)
      - Too many numbers causes a syntax error
- Lastly, we can set the number of variables using the initializer list of literals
  - EX:
    - `int x[] = {1,2,3};`

---

---

---

---

---

---

---

---

## An Example

```
#include <stdio.h>
#include <stdlib.h>
#include <time.h>
#define SIZE 7

int main() {
    int face; //die value
    int roll; //num of rolls
    int freq[SIZE] = {0};

    srand(time(NULL)); //seed random # generator

    for (roll = 1; roll <= 5000; roll++) {
        face = 1 + rand() % 6;
        freq[face]++;
    }
    //ideally it would do something with the freq array!
```

---

---

---

---

## Arrays & Functions

- Arrays are passed by reference, and their elements are then passed by value
  - So if you modify the elements of the array in a function, you've modified the elements of the array
- We'll discuss when we get to pointers why this happens and mechanisms to avoid this

CSF 35/457 Systems Programming

---

---

---

---

---

---

## Gnome Sort

- Gnome Sort is based on the technique used by the standard Dutch Garden Gnome (SimpleSort)
- Here is how a garden gnome sorts a line of flower pots.
  - Basically, he looks at the flower pot next to him and the previous one;
    - if they are in the right order he steps one pot forward, otherwise he swaps them and steps one pot backwards.
  - Boundary conditions: if there is no previous pot, he steps forwards; if there is no pot next to him, he is done.

CSF 35/457 Systems Programming  
Introduction to Arrays & Pointers  
Reading: 180

Michael Ruth, Ph.D.  
mruth@roosevelt.edu  
9

---

---

---

---

---

---

---

---

## Actual Gnome Sort Code

```
void gnomesort(int n, int ar[]) {
    int i = 0;
    while (i < n) {
        if (i == 0 || ar[i-1] <= ar[i])
            i++;
        else {
            int tmp = ar[i];
            ar[i] = ar[i-1];
            ar[--i] = tmp;
        }
    }
}
```

---

---

---

---

---

---

---

---

## More-Dimensions

- Sometimes (read often) you need more than one dimension
  - Images are multidimensional
    - B&W images are 2x2
    - Color images are 2x2x3
  - GIS stuff is even more dimensional
    - Longitude, latitude, depth
      - And often multiple readings such as
        - » Salinity
        - » Wave Height
        - » Etc
- So we need a way to model this with arrays

---

---

---

---

---

---

---

---

## Yet Another Example

```
double avgSalinity(int area[][][], int long, int lat, int
depth) {
    int i,j,k;
    int sum = 0;
    for (i=0; i<long; i++) {
        for (j=0; j<lat; j++) {
            for (k=0; k<depth; k++) {
                sum += area[i][j][k];
            }
        }
    }
    return (sum/(long*lat*depth));
}
```

---

---

---

---

---

---

---

---

## Pointers

- Pointer basics (notation and use)
- Defining Moments, Assignments, etc
- Pointers and Arrays
- Pointers and Functions
- Complicated Declarations & Other

---

---

---

---

---

---

---

## Pointer Introduction

- Pointers are easily the most powerful feature of the C programming language
  - But the *hardest to master*
- Pointers enable
  - Programs to simulate call by reference
  - Create and manipulate dynamic data structures
- Pointers are variables whose *values are memory addresses*
- A variable name directly references a value whereas a pointer indirectly references a value thus referencing a value through a pointer is called indirection

---

---

---

---

---

---

---

## Pointer Definition

- Like all variables, pointers must be defined before use
- Pointer definition follows the following syntax
  - `<pointerType> *<varname>`
  - And we say that pointer varname points to an object of pointerType

---

---

---

---

---

---

---

## Pointer Assignment

- Pointer assignment takes one of the following forms:

```
/* an address (here of <someVariable> */  
<pointerVarName> = &<someVariable>
```

```
/* NULL (preferred) NULL is in stdlib */  
<pointerVarName> = NULL;
```

```
/* NULL */  
<pointerVarName> = 0;
```

---

---

---

---

---

---

---

---

## Pointer Basics (notation)

```
/* defining a variable */  
int a = 7;
```

```
/* defining a pointer */  
int *aPtr;
```

```
/* assigning to a pointer */  
aPtr = &a;
```

---

---

---

---

---

---

---

---

## Address Operator

- & operator
  - Returns the address of a variable

```
/* address of aPtr */  
&aPtr == 55000;
```

```
/* address of a */  
&a == 65000
```

---

---

---

---

---

---

---

---

## De-Referencing Operator

- `*` operator
  - defines a pointer
  - get/set the value of variable

`/* Dereference aPtr */`

`*aPtr = 8;`

---

---

---

---

---

---

---

---

## Pointers and Arrays

- Key points:
  - Arrays are contiguous blocks of memory in C
  - The variable of an array type can be used as the address of the 0th element

• Thus:

```
-int a[5]; int *aPtr;  
-aPtr = &a[0] ≈ aPtr = a;
```

---

---

---

---

---

---

---

---

## Pointer 'Rithmetic

- Pointer arithmetic only makes sense when using pointers as arrays
- Pointer Math Basics
  - Increment/Decrement pointers
  - Integer added to/subtracted from a pointer
  - A pointer may be subtracted from another pointer

---

---

---

---

---

---

---

---

## Increment/Decrement

```
int a[5]; int *aPtr; aPtr = a;  
/* aPtr == 65000 */
```

```
*aPtr++ == a[1];  
/* aPtr is now 65004 */
```

```
*aPtr-- == a[0];  
/* aPtr is now 65000 */
```

---

---

---

---

---

---

---

---

## Adding an Integer to a pointer

```
int a[5]; int *aPtr; aPtr = a;  
/* aPtr == 65000 */
```

```
*(aPtr + 3) == a[3];  
/* aPtr is now 65012 */
```

---

---

---

---

---

---

---

---

## Adding/subtracting a pointer to/from a pointer

```
int a[5]; int *aPtr;  
aPtr = a; aPtr2 = &a[3];  
/* aPtr == 65000 */  
/* aPtr2 == 65012 */
```

```
aPtr2 - aPtr = ?  
//65012 - 65000 = 12  
//65012 - 65000 = 12/4 =  
3
```

---

---

---

---

---

---

---

---

## Pointers & Dynamic Arrays

- Arrays by themselves are static in C
- Using pointers we can develop dynamic arrays
- For instance:
  - `int *arr;` vs `int arr[5];`
- To initialize:
  - we can pretend it's an array:
    - `int *arr = "To be or not to be";`
  - Or we can use malloc and assignment:
    - `int *arr = malloc ( sizeof(int) * 5 );`

---

---

---

---

---

---

---

## Dynamic Memory Allocation

- **malloc**
  - `*void malloc(<sizeInBytes>)`
  - ie:
    - `aPtr = (int *)malloc(sizeof(int)*5)`
- **calloc**
  - `*void calloc(<number>,<baseSizeInBytes>)`
  - ie:
    - `aPtr = (int *)calloc(5,sizeof(int))`

---

---

---

---

---

---

---

## Call-By Differences and Pointers

- Call-By-Value is default. However, this is not always ideal. Why?
- Pointers are the how for C and Call-by-reference.
- However, unrestricted access to the variable may not be ideal either. Why?
- Variations between pure call by value and pure call by reference involve the **const** keyword in C

---

---

---

---

---

---

---

## Additional Array/Pointer Notation

- Additional but important notation
- Given: `int a[5]; int *aPtr; aPtr = a;`
- The following are all equivalent:

## const qualifier

- Informs the compiler that the variable should not be modified
- Was not part of original C standard
- Usage will be described as we discuss the passing pointers to function mechanisms
  - Constant pointer to constant data
  - Constant pointer to non-constant data
  - Non-constant pointer to constant data
  - Non-constant pointer to non-constant data

## Constant Vs Non-Constant

- Constant pointer
  - Address location pointer points to cannot be modified
  - Assuming `int *aPtr;` is passed to function
  - `aPtr = &<someOtherVariable>` is not allowed
- Constant Data
  - Data at address cannot be modified
  - Assuming `int *aPtr;` is passed to function
  - `*aPtr = <someValue>` is not allowed

---

---

---

---

---

---

---

---

## Non-Constant Pointer & Data

- Highest level of data access
- No use of `const` qualifier, thus is the default for passing pointers to functions
- Example
  - `void function1(int *aPtr)`

## Example of non-constant pointer & data

```
/* convert string to uppercase letters */
void convertToUpper( char *sPtr )
{
    /* current character is not '\0' */
    while ( *sPtr != '\0' ) {
        /* if character is lowercase, */
        if ( islower( *sPtr ) ) {
            /* convert to uppercase */
            *sPtr = toupper( *sPtr ); //value change
        } /* end if */
        /* move sPtr to the next character */
        ++sPtr; //pointer change
    } /* end while */
} /* end function convertToUpper */
```

## Example of non-constant pointer & data (cont)

```
int main()
{
    /* initialize char array */
    char string[] = "characters and $32.98";
    printf( "The string before conversion is: %s", string );

    convertToUpper( string );
    printf( "\nThe string after conversion is: %s\n",
        string );

    return 0; /* indicates successful termination */
} /* end main */
```

## Non-Constant Pointer to Constant Data

- EX:
  - `void function2(const char *sPtr)`
- Pointer can be modified, but what the pointer points to cannot.
- Process each element of an array without modifying it

## Example of non-constant pointer to constant data

```
/* sPtr cannot modify the character to which it points,
   i.e., sPtr is a "read-only" pointer */
void printCharacters( const char *sPtr )
{
    /* loop through entire string */
    for ( ; *sPtr != '\0'; sPtr++ ) { //pointer moves
        printf( "%c", *sPtr );
    } /* end for */
} /* end function printCharacters */
```

## Example of non-constant pointer to constant data (cont)

```
int main()
{
    /* initialize char array */
    char string[] = "print characters of a string";

    printf( "The string is:\n" );
    printCharacters( string );
    printf( "\n" );

    return 0; /* indicates successful termination */
} /* end main */
```

## Constant pointer to non-constant data

- Pointer always points to the same location in memory, and the data it points to can be modified (default for an array name)
- Must be initialized upon declaration
  - `int * const ptr = &x;`
- Typically, used in array notation use functions

## Constant pointer to non-constant data EX

```
int main() {  
    int x; /* define x */  
    int y; /* define y */  
  
    /* ptr is a constant pointer to an integer that can be  
    modified  
    through ptr, but ptr always points to the same  
    memory location */  
    int * const ptr = &x;  
  
    *ptr = 7; /* allowed: *ptr is not const */  
    ptr = &y; /* error: ptr is const; cannot assign new  
    address */  
  
    return 0; /* indicates successful termination */  
} /* end main */
```

## Constant Pointer To Constant Data

- Least access privilege
- Always points to the same memory location and the data value at that location may not be modified
  - `const int *const ptr = &x;`
- Should be passed to a function which only accesses the pointers using array subscript notation and does not modify the array

## Constant Pointer To Constant Data EX

```
int main()
{
    int x = 5; /* initialize x */
    int y;     /* define y */

    /* ptr is a constant pointer to a constant integer. ptr
       always points to the
       same location; the integer at that location cannot
       be modified */

    const int *const ptr = &x;

    printf( "%d\n", *ptr );

    *ptr = 7; // error: *ptr is const; no new value
    ptr = &y; // error: ptr is const; no new address

    return 0; /* indicates successful termination */
} /* end main */
```

Michael Ruth, Ph.D.  
mruth@roosevelt.edu  
40

## Compile time errors & const

- The error message presented by attempting to modify a variable which cannot be modified is:

```
- <filename>(<lineNumber>) : error <errorNo>: l-value
  specifies const object
```

mruth@roosevelt.edu  
41

## Pointers to Functions

- A pointer can point to a function
- The pointer contains the address of the function in memory
- Very similar to array names, function names are the starting address in memory of the code that performs the function's task
- Similar in concept to Java's Comparator
- Used in sorting, menu driven applications, etc

## Pointers to Function EX (1)

```
/* prototypes */
void bubble( int work[], const int size,
             int (*compare)( int a, int b ) );
int ascending( int a, int b );
int descending( int a, int b );
void swap( int *element1Ptr, int *element2Ptr );

int ascending( int a, int b )
{
    return b < a;    /* swap if b is less than a */
} /* end function ascending */

int descending( int a, int b )
{
    return b > a;    /* swap if b is greater than a */
} /* end function descending */
```

## Complicated Declarations

- The Key to decipher complicated declarations are C's operator precedence rules
- Does everyone have a copy of these?
  - If not, I'll post them.
- Some examples of complicated declarations:
  - `char (*(*x())[])()`
    - x: function returning pointer to array[] of pointer to function returning char
  - `char (*(*x[3])())[5]`
    - x: array[3] of pointer to function returning pointer to array[5] of char
- I am sorry to inform you that these exist in reality
